1 Introduction

Rendering realistic images is a challenging task, specially if there are memory or time constraints for the computation. Cloth is a complex material composed of interwoven threads of different types. Moreover, its appearance can vary from diffuse to highly specular.

2 Previous work

Solving global illumination generally involves providing a solution to the rendering equation [3]. One of the earliest approaches was based on simple empirical shading models [9]. The main objective was to accomplish believable shading, disregarding physical accuracy.

The methods can be broadly divided into three groups, data based models, geometric models and volumetric models.

The data based approach focuses on collecting reflectance information, that will be later used to model the cloth. Bidirectional Texture Function (BTF) [1] is a function that is often used to be sampled in the data based techniques.

Geometric models focus on simulating the micro-geometry of the cloth in conjunction with global illumination. The light scattering is simulated for each fibre in the thread, where the fibres are modelled as perfect cylinders. To be able to model the complete scattering effects on a surface, Bidirectional Scattering-Surface Reflectance Distribution Function (BSSRDF) [5] have been used. With this function, complex light phenomena like subsurface scattering are modelled.

3 Methodology

In this section we will discuss in detail the theoretical and practical aspects of the chosen paper.

3.1 Light scattering model

We have chosen to implement a recent paper [6] which presents a microcylinder based model for fast and realistic cloth rendering. The authors propose a model of fabric based on two

microcylinders oriented in two orthogonal directions, as shown in Figure 1. Sadeghi et al. define the reflectance model for a single thread in the fabric as

Figure 1: Sadeghi et al. shading model [6], where ω_i is the incident light direction, \mathbf{n} is the surface normal and $\mathbf{t}_1, \mathbf{t}_2$ are the orthogonal thread directions.

Figure 2: Sadeghi et al. shading model [6], showing θ and ϕ angles given a pair of directions ω_i and ω_r .

$$L_r = \int \frac{(f_{r,s}(\mathbf{t}, \omega_i, \omega_r) + f_{r,v}(\mathbf{t}, \omega_i, \omega_r)) L_i(\omega_i) \cos(\theta_i) \delta \omega_i}{\cos^2(\theta_d)}, \quad (1)$$

where \mathbf{t} is the thread direction, ω_i is the ray incoming direction, ω_r is the ray outgoing direction, $\theta_i, \theta_r, \phi_i$ and ϕ_r are angles as shown in Figure 2, $\theta_d = \theta_i - \theta_r$ and L_i is the incoming irradiance in the evaluated point. Note that radiometric notation [4] is used to define L_r , which represents the outgoing radiance over a infinitesimal arc length of the cylinder and how the integral extends over the entire sphere instead of the typical hemisphere.

The surface reflection term in Equation 1 is defined as

$$f_{r,s}(\mathbf{t}, \omega_i, \omega_r) = F_r(\eta, \omega_i) \cos(\phi_d/2) g(\gamma_s, \theta_h), \quad (2)$$

where $\theta_h = (\theta_i + \theta_r)/2$, $\phi_d = \phi_i - \phi_r$, F_r is a Fresnel reflection term that is computed using Schlick's approximation [7] $F_r(\eta, \omega_i) = \eta + (1 - \eta)(1 - \mathbf{h} \cdot \omega_i)^5$ where \cdot is the vector dot product operator, $\mathbf{h} = (\omega_i + \omega_r) / |\omega_i + \omega_r|$ is the normalized halfway vector, η is the reflectance for $\mathbf{h} \cdot \omega_i = 1$, $g(\gamma, \theta) = \gamma e^{\mathbf{v} \cdot \mathbf{p} - 1}$ is a Gaussian lobe [8] where \mathbf{p} is the lobe axis, the direction \mathbf{v} is the spherical parameter in the resulting function and γ is the amplitude.

The volume scattering term in Equation 1 is defined as

$$f_{r,v}(\mathbf{t}, \omega_i, \omega_r) = F_t(\eta, \omega_i) F_t(\eta', \omega'_r) \frac{(1 - k_d) g(\gamma_v, \theta_h) + k_d \mathbf{k}_a}{\cos(\theta_i) + \cos(\theta_r)}, \quad (3)$$

where k_d is a scattering constant, \mathbf{k}_a is an rgb albedo constant vector, $F_t = 1 - F_r$ is a Fresnel transmission term, ω'_r is a projection of ω_r into a plane that contains the normal \mathbf{n} and η' is computed using the Bravais index [4] as $\eta'(m) = \sqrt{\eta^2 - \sin^2(m)} / \cos(m)$ where m is the angle between ω_r and its projection ω'_r .

The outgoing radiance in the path shown in Figure 2 is

$$L_r(\omega_r) = a_1 L_{r,1}(\omega_r) + a_2 L_{r,2}(\omega_r), \quad (4)$$

where a_1 and a_2 are the area coverage ratio for the first and second thread within the patch, in our case we assume a watertight pattern of equally size threads, leading to $a_1 = a_2 = 0.5$, L_1 and L_2 are the outgoing radiances for the first and second thread computed as shown in Equation 1.

In order to compute a thread direction \mathbf{t} without using external data structures, we follow a fixed texture axis as shown in Figure 3. Given an intersection point in a triangle $\mathbf{p} = [x_p, y_p, z_p]$ and its texture coordinates $\mathbf{u} = [u_p, v_p]$. We define \mathbf{t} vector as the vector $\mathbf{t} = (\hat{\mathbf{p}} - \mathbf{p}) / |\hat{\mathbf{p}} - \mathbf{p}|$ such that $\hat{\mathbf{p}}$ texture coordinates are $\hat{\mathbf{u}} = [u_p + 1, v_p]$. In our shader we can easily compute the texture coordinates of the triangle vertices, however we can not immediately get a world position from a new texture coordinate. Assuming that the 3d to texture transformation is an affine matrix T ,

$$\mathbf{u}T = \mathbf{p} \rightarrow \begin{pmatrix} u & v \end{pmatrix} \begin{pmatrix} a & b & c \\ d & e & f \end{pmatrix} = \begin{pmatrix} x & y & z \end{pmatrix} \quad (5)$$

Figure 3: To compute the vector \mathbf{t} , we follow the texture coordinates of the intersection point \mathbf{p} .

The system in Equation 5 has six unknowns and three equations, therefore we need two pairs of world points - texture coordinates to solve T . Writing out the terms for two known points \mathbf{p}_1 and \mathbf{p}_2 in the triangle,

$$\begin{aligned} x_1 &= u_1 a + v_1 d, & y_1 &= u_1 b + v_1 e, & z_1 &= u_1 c + v_1 f, \\ x_2 &= u_2 a + v_2 d, & y_2 &= u_2 b + v_2 e, & z_2 &= u_2 c + v_2 f. \end{aligned} \quad (6)$$

Solving for each term analytically,

$$d = \frac{u_2x_1 - u_1x_2}{u_2v_1 - u_1v_2}, \quad e = \frac{u_2y_1 - u_1y_2}{u_2v_1 - u_1v_2}, \quad f = \frac{u_2z_1 - u_1z_2}{u_2v_1 - u_1v_2}, \quad (7)$$

$$a = \frac{x_1 - v_1d}{u_1}, \quad b = \frac{y_1 - v_1e}{u_1}, \quad c = \frac{z_1 - v_1f}{u_1}. \quad (8)$$

Notice that the term of $1/(u_2v_1 - u_1v_2)$ is shared, so it can be precomputed in order to increase performance. The aforementioned method will give \mathbf{t}_1 , for \mathbf{t}_2 the process is equivalent with the exception that $\hat{\mathbf{u}}$ will be incremented on the v direction, $\hat{\mathbf{u}} = [u_p, v_p + 1]$.

3.2 Shading model

In order to render cloth fabrics the authors evaluate the outgoing radiance from each patch, which is assumed to be locally flat and smaller than a pixel in the image. This patch is defined as the smallest thread weaving patten such that the fabric can be constructed by repeating this patch. For each thread in the patch a tangent curved is defined, this curve will be sampled at fixed positions giving the normal direction in that position, with it the BRDF will be evaluated and the total outgoing radiance can be computed as follows,

$$L_r() \quad (9)$$

3.3 Other implementation considerations

In order to compute more easily quantities such as the θ or ϕ angles introduced in the previous section, we will defined a new coordinate system with the vectors $\{\mathbf{t}, \mathbf{n}, \mathbf{s}\}$, whose centre will be the triangle ray-intersection point \mathbf{p} , where \mathbf{s} is a normalized vector $\mathbf{s} = \mathbf{n} \times \mathbf{t}$ and \times is the vector cross product operator. The matrix that will transform from world coordinates to this system is

$$M = M_{trans}M_{rot} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -p_x & -p_y & -p_z & 1 \end{pmatrix} \begin{pmatrix} t_x & n_x & s_x & 0 \\ t_y & n_y & s_y & 0 \\ t_z & n_z & s_z & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad (10)$$

such that $\mathbf{x}M = \mathbf{x}'_{new}$, where \mathbf{x} is the original row vector in homogeneous coordinates and \mathbf{x}'_{new} is the transformed vector.

We decided to implement the shader in Maya'sTMMental RayTMrendering software. The rationale under this choice lays in the advantages of integrating work in a established framework, which allows us to easily use the shader for a dynamic cloth simulation. Mental RayTMapproximates Kajiya's equation [3] using photon mapping [2]. Our approach is to compute an initial estimate of the outgoing radiance L_{ri} for each direct hit during the ray-tracing path. In the photon map construction stage each photon hit will locally sample L_{ri} using Equation 1, from this samples an average irradiance will be evaluated, which will then be added to the initial estimate as shown below

$$L_r = L_{ri} + \sum_{i=1}^I \psi_i L_{ri}, \quad (11)$$

where I is the total number of photons inside a fixed radius around \mathbf{p} and ψ_i is the normalized flux of the i th photon, which is computed from an initial arbitrary flux shared by all photons and decreases with an absorption rate per bounce.

TODO Add analysis of the current paper, what is it based on, what is it actually modelling, what are the limitations, etc
